## What is Technical Debt?

- A metaphor introduced by Ward Cunningham in 1992
- Describes the pending effort of maintenance that is needed to reach a certain quality level
- Is subject in many former works
- Necessary for statements:  
A model for quantifying and measuring technical debt

## Why another approach?

- Planning and issue tracker data from major German software manufacturer
- Easy and fast
- Comparison of different development states
- Analysis of technical debt and efficiency for the different stages

# Outline

- 1 Motivation
- 2 Project Data
- 3 Technical Debt Metric
  - Measuring Technical Debt
  - Quality Level
  - Efficiency
- 4 Application
- 5 Discussion

# Two different states

## Normal State

- Stages A, B1, B3 and C
- normal development process

## State of Emergency

- Stage B2
- focus on features

## Provided Data - Important fields

**IssueType** The type of a certain issue (*User Story*, *Defect* or *Feature*).

**EffortSec** The real effort that was spent to implement a feature, user story or to fix a defect, depending on the issue type.

**IssueKey** The issue's unique key to identify it.

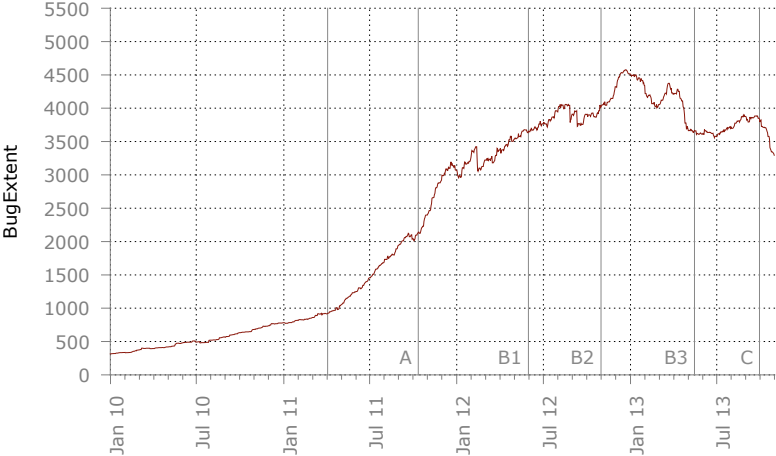

**FeatureKey** The parent ID. If a user story is assigned to a parent feature, this feature's IssueKey is stored here.

**CreationDate** The date the issue was created.

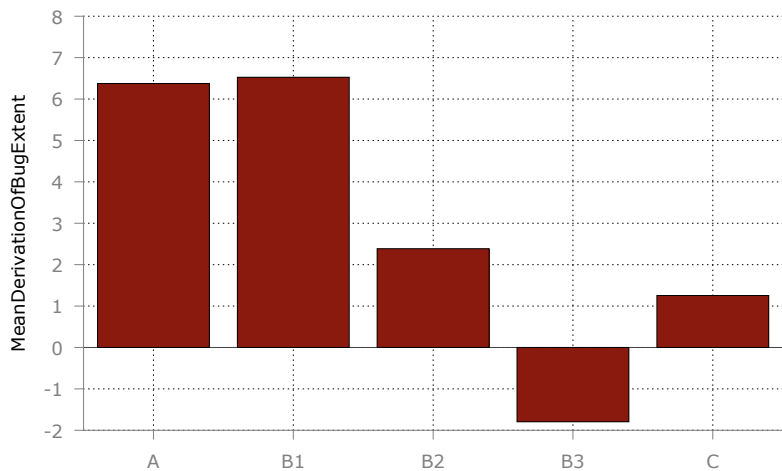

**ComplDate** The date the issue has been completed.

# Bug Extent

## Mean derivate of Bug Extent

# Feature Extent

# Mean derivate of Feature Extent

# Measuring Technical Debt

## Bug Count

$$d(t) := n_{bug}(t)$$

## Bug Extent

$$d(t) := \sum_i^{n_{bug}(t)} e_{bug,i} \cdot s_{bug,i}$$

$e_{bug}$  Real effort in days to fix a bug

$s_{bug}$  Severity of a bug

# Quality Level

$$\text{QualityLevel} = \frac{\text{Proceeds}}{\text{Deficiency}}$$

## Feature Extent

$$f(t) := \sum_i^{n_{\text{feat}}(t)} e_{\text{feat},i} \cdot s_{\text{feat},i}$$

$n_{\text{feat}}(t)$  All completed features at time t

$e_{\text{feat}}$  Real effort in days

$s_{\text{feat}}$  Importance of a feature

## Quality Level

$$q(t) := \frac{f(t)}{d(t)}$$

# Efficiency

## Efficiency

$$Eff(\Delta t) := \frac{e_{push}}{c_{team} \cdot \Delta t}$$

$e_{push}$  Effort for all completed features

$c_{team}$  Costs for team

## Normed Efficiency

$$\overline{Eff}(\Delta t) := Eff \cdot \left( 1.0 + \frac{q(t_1) - q(t_0)}{|q(t_{end}) - q(t_{start})|} \right)$$

$t_0$  Start of the current stage

$t_1$  End of the current stage

$t_{start}$  Global start across all stages

$t_{end}$  Global end across all stages

# Outline

# Quality Level

# Efficiency

# Normalized Efficiency

# Normalized Efficiency

# Outline

- 1 Motivation
- 2 Project Data
- 3 Technical Debt Metric
  - Measuring Technical Debt
  - Quality Level
  - Efficiency
- 4 Application
- 5 Discussion**

## Discussion

- Bug Extent is much more significant than Bug Count
- Feature Extent is increasing (In B2 it is faster rising than in the other stages)
- The resulting quality level is rising shakily
- In B2 the absolute efficiency was the highest
- Even after normalizing with the quality level B2 has still the best efficiency

# Limits

- In our example we assumed same severity for all bugs and all features.
- Effort for closing bugs calculated for last stage, even if bug was fixed during more than one stage
